One of the key areas of any radio system is that part where the signal is transferred from the transmitter to the receiver. This involves the use of antennas or aerials to radiate the signal as an electromagnetic wave, and then there is the way that the electromagnetic wave travels or propagates between the transmitting antenna and the receiving one. Thus antennas and propagation are key areas for any radio system.

The Wave Propagation and Antennas Subcourse is designed to teach the knowledge necessary to identify characteristics of wave propagation and calculating antenna lengths. Additional information is contained concerning types of antennas, and frequency selection procedures for short and long distance radio circuits.

RADIO WAVE PROPAGATION AND ANTENNAS

Maximum distance between two antennas for LOS propagation: $\bullet h_1 = \text{height of antenna one}$ $\bullet h_2 = \text{height of antenna two}$ $3.57(\sqrt{h_1} + \sqrt{h_2})$

Antennas & Propagation

RF propagation is a particularly important topic for any radio communications system. The radio propagation will depend on many factors, and the choice of the radio frequency will determine many aspects of radio propagation for the radio communications system.

What is Radio Propagation: RF Propagation » Electronics Notes

Here the Ham Radio Antenna Propagation is slightly different. 10 - 20 meter bands are happy as the D-layer does not effect the higher frequencies as much and these signals go up much higher into the atmosphere and reflect off of the E and F layers providing long DX contacts anywhere on the earth. Especially during sunspot maximums.

Ham Radio Propagation

In radio engineering, an antenna is the interface between radio waves propagating through space and electric currents moving in metal conductors, used with a transmitter or receiver.

Antenna (radio) - Wikipedia

Line-of-sight propagation means radio waves which travel in a straight line from the transmitting antenna to the receiving antenna. Line of sight transmission is used to medium range radio transmission such as cell phones , cordless phones , walkie-talkies , wireless networks , FM radio and television broadcasting and radar , and satellite communication , such as satellite television .

Moreover, new advanced antenna systems, such as very large antenna arrays, will be required to overcome the very high path loss over the radio channel. The antennas in an mm-Wave and THz band need to support a very large bandwidth from several GHz up to a few THz , for example, sub-THz band communication systems at 300. GHz can provide a relative bandwidth of 10% at the centre frequency, i.e., in the order of 30 GHz.

As amateur radio operators, generally engaged in terrestrial radio communication, we normally use linear polarized antennas. This is applicable to both HF as well as VHF/UHF communication. Typically, our antennas are oriented in ways to favor either Vertical or Horizontal polarization.

The polarisation of a radio wave is in the direction of the electrostatic (electric) Field of the Antenna. A horizontal antenna radiates a horizontally polarised wave whereas a vertical Antenna will radiate a vertically polarized wave.
